1 **Abstract**

2 The present study investigated the rehydration kinetics of dried pumpkin slices issued from
3 different drying operations, namely airflow drying (AFD), freeze-drying (FD), Vacuum Multi
4 Flash Drying (VMFD) and Swell-drying (SD) which inserts Instant Controlled Pressure Drop
5 (DIC) Texturing between two AFD stages (AFD+DIC+AFD). Rehydration process depends on
6 dehydration methods. It has been noticed that the slowest rehydration process has been
7 observed for AFD whilst VMFD, FD, and SD averred short rehydration time. Experimental
8 rehydration curves were performed through empirical and diffusion models. Hence, it has
9 been noticed that Weibull has provided the best rehydration fitting curve. In other hand,
10 Fick's diffusion models were also used to describe kinetics of rehydration process. They were
11 characterized by two effective diffusivity coefficients D_{eff_1} and D_{eff_2} for AFD and VMFD, and
12 three effective diffusivity coefficients in the case of FD and SD (AFD+DIC+AFD). The
13 temperature dependence of the diffusivity coefficients was also described by Arrhenius-type
14 relationship, with adequate activation energy levels.

15 **Keywords:** rehydration; empirical models; diffusive models; mass transfer; pumpkin slices.

16

17 **1. Introduction**

18 Drying is one of the most conventional and largest scale processes of food preservation. A
19 significant number of dried products are either directly consumed or used in food industry. It
20 may preserve a high level of nutritive values of vegetables and can be used in tremendous
21 receipts, widely defined in fresh, warm, frozen, and stir soups (Rehydration Chart®, 2016).
22 Thus, rehydration of dried vegetable is the process which is necessary for restoring raw
23 product properties, by soaking into water in the way that the final product can take the
24 initial raw material characteristics (Krokida and Philippopoulos 2005). In this view, several
25 newly food dehydration techniques were proposed during the last years. The main
26 objectives were to allow the dried food product in preserving its initial nutrition value, in
27 easily recovering its initial state through rehydration process, then after in reducing the cost.
28 Accordingly, Airflow drying technique is considered as among the highest cost effective,
29 economically viable hydration process. However, the drawbacks consist on high temperature
30 demand for long duration, which can be the cause of final product quality deterioration
31 (Saravacos 1967). The low product quality is mainly due to the high compact texture,
32 generated from the shrinkage phenomenon. Moreover, the compact structure can
33 dramatically reduce the drying rate which may cause an important thermal degradation, loss
34 of vitamin, color and flavor (Mounir et al. 2012).

35 Freeze-drying is defined as the dehydration operation capable to replace water by air
36 without any shrinkage process, thus, leading to high-porosity dried material. Hence, the
37 freeze-dried material gets the most adequate rehydration behavior (Caparino et al. 2012).
38 Moreover, FD is generally considered as the best method for high quality dried food
39 production (Ratti 2001). However, the drawback of this approach is the higher production

40 cost, caused by the high energy consumption, along the process time, leading to low
41 efficiency (Ratti 2001; Hsu et al. 2003; Speranza et al. 2017).

42 Recently two developed technologies have been adopted for dehydration of fruits and
43 vegetables: The swell-drying SD, which combines the use of instant controlled pressure drop
44 (DIC) texturing between two stages of conventional airflow drying AFD, and the Dehydration
45 by Successive Pressure drops (DDS) or Vacuum Multi-Flash Dehydration VMFD process.

46 These two technologies are distinguished by their capacity to handle a wide range of food
47 products regardless, their heat sensitivity.

48 Controlled-textured highly-poured Swell-Dried material allows to reach quickly and deeply
49 the final drying process stage, thus reducing both the energy consumption and the
50 manufacturing cost (Allaf et al. 2012). Moreover, the rehydration process is quickly achieved,

51 due to porous texture. However, the availability of flavonoids and antioxidant activity are
52 often much higher than those existing in crude raw matter (Mounir et al. 2014).

53 Furthermore, DIC products have normally longer lifetime duration due to insects and larva
54 absence, whereas, the storage may exceed one and even two years (Allaf and Allaf 2014a).

55 Vacuum Multi-Flash Drying technology (VMFD) has been implemented and evaluated for
56 drying vegetables which are sensitive to the heat (Mounir et al. 2011; Louka and Allaf 2004a;

57 Louka et al. 2004b), snack preparation, etc. (Yagci and Evci 2015). VMFD (Mounir et al. 2012)
58 induces high-quality of dehydrated product with greater preservation of nutriment, less
59 degradation on product color, texture, etc., and higher kinetics of both drying and
60 rehydration (Gutierrez-Pacheco et al. 2016; Sehwat et al. 2016).

61 Because of the vast variety of dehydrated food available to consumer and the need to satisfy
62 food quality standards whilst reducing energy consumption, a deep understanding of the

63 concerned processes is required in order to obtain their perfect optimization (Vega-Gálvez,
64 et al. 2009).

65 Within this frame, mathematical models are efficient tools to design and optimize both
66 hydration and rehydration operations. Several empirical models were used in modeling the
67 mass transfer kinetic, during rehydration process. Recently, these models have been
68 adopted by numerous researchers, due to their powerful and simplicity, whereas the
69 obtained results can be used in the process optimization. The studied food products
70 comprise figs (Ansari et al. 2015), morchella esculenta (morel) (Garcia-Pascual et al. 2006),
71 quinces (Noshad et al. 2011), cassava chips (Ajala et al. 2015; Athanasia and Konstantinos
72 2009), carrots (Planinic et al. 2005), red pepper (Demiray and Tulek 2017), rosa rubiginosa
73 fruits (Ohaco et al. 2015), basil (Demirhan and Özbek 2010), shiitake mushroom (Lentinus
74 edodes) (García-Segovia et al. 2011), lens culinaris (Oroian, 2017), tef flour breakfast cereal
75 (Solomon 2008), Chilean Papaya (Zura et al. 2013a), broccoli (Sanjuan et al. 1999), potato
76 cubes (Salimi Hizaji et al. 2011), potato cylinders (Cunningham et al. 2008), Potato slices
77 (Ghosh and Gangopadhyay 2004), onion (Debnath et al. 2004) and apple (granny smith)
78 slices (Zura-Bravo et al. 2013b). In this view, this work investigates the water temperature
79 influence on rehydration kinetic of pumpkin slices, using four different drying methods
80 namely; (AFD, VMFD, SD combining AFD+DIC+AFD, and FD). Furthermore, different empirical
81 models have been assessed for better describing the process.

82 **2. Materials and methods**

83 **2.1. Samples Preparation**

84 Pumpkin was fetched from local central market of La Rochelle. Prior to any treatment, it is
85 cut into several 3-mm thick slices using a dedicated vegetable robot cutter of type

86 (vegetable cutter CL- 50 Ultra-Robot-Cutter 230 Volts, N = 375 tr/min). The initial water
87 content (wet basis) of pumpkin was about 87%. The measurements were achieved using an
88 adequate drying oven at 105°C for 24 hours (AOAC 1990).

89 **2.2. Drying Methods**

90 The pumpkin slices were arranged into four batches (Figure 1); i/ the first batch for airflow
91 drying (AFD), ii/ the second for drying with successive pressure (VMFD), whereas iii/ the
92 third for Swell-Drying (SD) and iv/ the fourth was performed through freeze-drying (FD).

93 **2.2.1. Airflow drying (AFD).**

94 The pumpkin slices were dried in a dedicated airflow dryer facility (Memmert: Four universal
95 UNB Model 800) at 60 °C. The airflow had an initial vapor pressure of 265 Pa and a velocity
96 of about 1.2 m/s. The slices were dried until a water content of about 0.03 g H₂O/g dry basis
97 (db). Then, the samples were enclosed in hermetically sealed bags.

98 **2.2.2. Freeze-drying (FD)**

99 Freeze-dryer equipment (SubliMate® BENCH TOP LABORATORY FREEZE DRYERS) was used to
100 dry pumpkin slices. The process was carried out through three different steps; i/ freezing in
101 room freezer (Whirlpool AFG 363/G) at -30°C and maintained for a period of 10 h, ii/
102 Sublimation at 7.4 Pa as absolute pressure with a low temperature freeze-dryer trap (-
103 52.5°C), and iii/ secondary Desiccation or desorption final drying stage for a period of 48h.
104 Subsequently, the freeze-dried samples were put in hermetically sealed bags.

105 **2.2.3. Swell-Drying SD by inserting Instant Controlled Pressure Drop (DIC) between two** 106 **stages of AFD**

107 Swell-Drying SD including a DIC texturing stage was carried out with;

108 i/ a first airflow drying AFD step at 60 °C with 265 Pa as airflow initial vapor pressure and
109 velocity of about 1.2 m/s until 0.18 g H₂O/g db: These partially-dried slices were enclosed in
110 hermetically sealed bags and put in a refrigerator at 4°C for 24h to make their water content
111 as homogenous as possible at 18% db which is the suitable level of moisture to allow DIC
112 texturing process to be adequate with pumpkin.

113 ii/ DIC texturing process: DIC cycle (Figure 2 (a)) started by a vacuum stage of 5 kPa as
114 absolute pressure (1→2). It facilitates the close contact between steam and sample surface.
115 Subsequently, saturated steam was injected into the reactor until an absolute pressure of
116 0.40 MPa (2→3). This level of high-pressure steam was maintained for 30 s (3→4). This high-
117 temperature/ high-pressure stage ended by instantaneously releasing the pressure towards
118 a vacuum (5 kPa) with a pressure drop rate $\Delta P/\Delta t > 0.5 \text{ MPa s}^{-1}$ (4→5).

119 Finally, the pressure has been released and settled at its atmospheric level (5→6) to allow
120 recovering the DIC textured samples;

121 iii/ Post-drying using AFD process, at 60 °C for about 3 h in order to obtain a final water
122 content in the range of 0.03 g H₂O/g db. These samples were preserved in hermitically
123 sealed bags.

124 **2.2.4. Dehydration using Successive Pressure Drops (Vacuum Multi-Flash Drying VMFD)**

125 VMFD process is a simple succession of low-temperature DIC cycles. Each VMFD cycle is
126 identical to DIC process (Figure 2 (b)). The batch of pumpkin slices has been partly dried with
127 airflow to 18% db under similar conditions to those described in AFD process. Subsequently,
128 the slices were put in hermitically sealed bags and stored in refrigerator at 4 °C for 24 h in
129 order to obtain a great homogeneity in terms of water content (about 0.18 g H₂O/g db).
130 Then, these partially dried slices were subjected to a fully automated VMFD unit (ABCAR-
131 VMFD Process, La Rochelle, France).

132 The study of VMFD process required recurrence of 50 cycles. Parameters of each VMFD cycle
133 was automated as follows: The highest air pressure level was maintained at $P^+ = 300$ kPa for
134 about $t^+ = 10$ s and ended by an instant pressure drop toward 100 kPa. The product is
135 maintained for about $t^- = 40$ s at the lowest gas pressure. After VMFD process, a convective
136 drying using hot air at 60 °C for a period of about 3 h follows in order to obtain final water
137 content within the range of 0.03 g H₂O/g db. These samples were preserved in hermitically
138 sealed bags.

139 **2.3. Rehydration experiments**

140 Rehydration experiments were carried out in distilled hot water bath. Three 400-ml
141 glassware, each one was filled with distilled water used to soak 2 g of slices of pumpkin
142 samples, dried according one of the above described drying method. Three different
143 temperature levels were adopted using water bath (MEMMERT, type: WNB 22 F. Nr.:
144 L509.0447) at 30, 45, and 60 °C, respectively for appropriate time duration. The weight of
145 samples was recorded every 5 min during the first 30 min, every 10 min for the second 30
146 min and every 30 min until reaching the mass transfer equilibrium. These experiments were
147 triplicated for all dried samples.

148 The moisture content of each sample was determined according to the conventional
149 standard (AOAC 1990), using drying oven and high-precision (0.0001 g) analytical-scale
150 balance (KERN & Sohn GmbH, type: ABJ 220-4NM). The experiments were also triplicated.

151 The rehydration ratios may be expressed as follows (Marabi and Saguy 2004):

$$RR = \frac{M_t - M_0}{M_e - M_0} \quad (1)$$

152 Where M_t , M_0 and M_e are the water content at time t , initial water content, and water
153 content at equilibrium, respectively; expressed by % dry basis db or g H₂O/g db).

154 **2.4. Modeling of Rehydration kinetic.**

155 **2.4.1. Phenomenological diffusion model**

156 Although phenomenological analysis of rehydration is mainly based on three processes
157 simultaneously: the imbibition of water into the dried material, the swelling and the leaching
158 of soluble, which is difficult to be investigated. Indeed, it may occur with various interactions
159 between water and solid matrix, with possibly anisotropic diffusivity depending on different
160 directions. To be more specific, as the water penetrates the slice matrix, sugar and other
161 soluble substances can be dissolved. Although, in the specific case of pumpkins, we may
162 assume that during the rehydration period, the water diffusion into the slices is the most
163 significant kinetics, and dissolution of some compounds is insignificant. Thus, it can be
164 assumed that the rehydration kinetics is controlled by the simplest transport of water, from
165 the surface to the slice core with an isotropic and homogeneous diffusion at constant
166 diffusivity value. Furthermore, the matrix sizes were assumed to keep constant value during
167 rehydration. Consequently, the mass transfer through pure diffusion is proportional to
168 concentration gradient of water content and the diffusion occurred with an effective
169 diffusion coefficient. Thus, the determination of latter coefficient is essential to better
170 describe mass transfer using similar Fick law, whose equation is expressed by (Vasić et al.
171 2016):

$$\frac{\partial MR}{\partial t} = \nabla [D_{eff} \nabla MR] \quad (2)$$

172 By assuming the value of D_{eff} as constant, it was possible to get:

$$\frac{\partial MR}{\partial t} = D_{eff} \nabla^2 MR \quad (3)$$

173 The pumpkin slice may be considered as a uniform plate that is subject to gradual non-
174 stationary regime with initial uniform distribution and equal concentration at the surface.

175 By assuming the matrix as undeformable (negligible shrink or expanded) infinite plate with
 176 uniform initial humidity distribution, negligible external resistance, and constant diffusivity,
 177 the analytical solution of the second law of Fick was developed by Crank (Crank 1975):

$$MR = \frac{8}{\pi^2} \sum_{n=0}^{\infty} \frac{1}{(2n+1)^2} \exp(-(2n+1)^2 \pi^2 D_{eff} t / 4L^2) \quad (4)$$

178 Where D_{eff} is the effective diffusivity (in m^2/s), t is time (in s), L half slice thickness (in m)
 179 and n is a relative integer.

180 For a sufficiently long-process time, all terms of the following sequence ($n \geq 1$) were assumed
 181 as negligible when compared to the first term. Hence the equation (4) can be assumed as
 182 follows:

$$MR = \frac{8}{\pi^2} \exp(-\pi^2 D_{eff} t / 4L^2) \quad (5)$$

183 The equation (5) can be rearranged and expressed as given as follows:

$$\ln(MR) = \ln\left(\frac{8}{\pi^2}\right) - \pi^2 D_{eff} t / 4L^2 \quad (6)$$

184 The drying experimental data values are represented in terms of $\ln(MR)$ versus rehydration
 185 time for different temperatures. The effective diffusivity is calculated as follows:

$$\text{Slope}(k) = -\pi^2 D_{eff} / 4L^2 \quad (7)$$

186 The influence of temperature on effective diffusivity may be expressed by an Arrhenius-type
 187 equation :

$$D_{eff} = D_{eff_0} \cdot \exp\left(-\frac{E_a}{RT}\right) \quad (8)$$

188 Where D_{eff_0} is the pre-exponential factor of the Arrhenius equation in (m^2s^{-1}), E_a is
 189 activation energy in ($J \text{ mol}^{-1}$), R is the universal gas constant ($8.314 \text{ J mol}^{-1} \text{ K}^{-1}$) and T is
 190 temperature (in K). From the slope of the straight line of $\ln(D_{eff})$ versus $1/T$, described by
 191 the Arrhenius equation (8), the activation energy, E_a , could be calculated.

192 **2.4.2. Empirical models**

193 Several authors have used empirical equation for rehydration process modeling. Among so
194 far suggested models, the most used models were those presenting the best simplicity and
195 mathematical convenience (Moreira et al. 2008). In particular, four empirical models have
196 been used to describe the rehydration kinetic (Table1). The model proposed by Peleg (1988)
197 (Eq. (9)) which consists of two parameter equation, non-exponential, used to describe the
198 rehydration kinetic. The model Peleg has been applied to rehydration for different type of
199 food products (Moreira et al. 2008). The Weibull distribution (Eq. (10)), describing the
200 process as a sequence of probability events, was found in wide applications of food
201 transformation, whereas it was proposed for rehydration process by several authors (García-
202 Pascual et al. 2006; Mujaffar and Lee Loy 2017). The exponential model (Eq. (11)) (Saguy et
203 al. 2005), and first order model (Eq. (12)) (Krokida and Marinos-Kouris 2003) have been also
204 used to describe the hydration characteristics of food materials. They are based on the
205 following assumptions: i/ The water temperature is constant during rehydration and ii/ The
206 initial water content of samples is uniform.

207 **2.5. Data statistical Analysis**

208 In the case of pumpkin slices, the experimental results obtained at three temperatures; 30,
209 45 and 60°C, were used to investigate, analyze, evaluate the model parameters, and identify
210 the most relevant model between these phenomenological equation (Eq. (2)) and the 4
211 mathematical empirical equations (Eq. (9-12)). The non-linear regression has been employed
212 with Levenberg-Marquardt procedure. Table 2 presents the values of these parameters
213 using determination coefficient (R^2), ki-square (χ^2) statistical test, and root mean square
214 error (RMSE), respectively defined as follows (Darvishi et al. 2013):

$$R^2 = 1 - \frac{\sum_{i=1}^N (RR_{exp,i} - RR_{pré,i})^2}{\sum_{i=1}^N (\overline{RR}_{exp} - RR_{exp,i})^2} \quad (13)$$

$$\chi^2 = \frac{\sum_{i=1}^N (RR_{exp,i} - RR_{pré,i})^2}{N - n} \quad (14)$$

$$RMSE = \sqrt{\frac{\sum_{i=1}^N (RR_{pré,i} - RR_{exp,i})^2}{N}} \quad (15)$$

215 With:

$$216 \quad \overline{RR}_{exp} = \frac{\sum_{i=1}^N RR_{exp,i}}{N}$$

217 Where RR_{exp} is the rate of experimental rehydration, RR_{pre} and the predicted rehydrated
 218 rate, N is the number of experimental points.

219 **3. Results and Discussion**

220 ***3.1. Effects of different drying processes on rehydration kinetics***

221 Dehydration process may engender changes in structure (shrinkage), rheological behavior,
 222 and chemical composition of vegetal tissues (Lewicki 1998). Since the rehydration is a
 223 complex process aiming to restore the properties of crude products once the dried product
 224 is put in contact with water and water vapor, the rehydration may be considered as a
 225 measure of wounds caused by drying and other pretreatment procedures. [The experimental](#)
 226 [data proved that the dried product behavior, during rehydration is depended on drying](#)
 227 [method.](#)

228 [The rehydration kinetic of pumpkin slices, obtained at different levels of temperatures](#)
 229 [through different drying methods Are shown by the Figs. 3 a\), 3 b\), and 3 c\).](#)

230 Whatever the rehydration temperatures, the SD and VMFD dried pumpkin slices presented
 231 higher rehydration ratio than AFD, but lower than freeze-dried FD. It was [also](#) found that the

232 DIC-textured products presented high effective rehydration diffusivity than that of AFD and
233 VMFD dried materials, but lower than that of freeze-dried FD, (Table 3). Porosity of both DIC-
234 textured and FD-dried were much greater than partially compact airflow dried slices.
235 Thus, the worst behavior of rehydration is attributed to AFD samples because it is correlated
236 with shrinking and thermal degradation due to such long-time high-temperature process.
237 Indeed, numerous research works have proven that faster rehydration process may result
238 from lower drying time and minimum shrinking (Cano-Chauca et al. 1974).
239 The porous texture and possibly open cells of DIC-treated materials result in higher water
240 diffusivity and hence in lower time of drying and rehydration. It is well known that the
241 degree of rehydration depends on the cellular structure deformation rate. Throughout the
242 drying, irreversible deformation and dislocation of cells were observed. This induced a loss
243 of integrity and therefore a dense structure of collapsed capillaries, and strong shrinkage.
244 Such reduced hydrophilic properties result in lower capacity of sufficiently absorbing
245 required water for a complete rehydration (Jayaraman et al. 1990).
246 The ability of reconstituting normal pieces principally depends on internal structure and
247 chemical composition of dried materials. It also depends on the possible damage that drying
248 can produce on the main constituents able to retain water (Protein and Starch) (Bremman et
249 al. 1990).
250 Maritza et al. (Maritza et al. 2012) have carried out different drying process effect study on
251 the physical and chemical properties of strawberry (*Fragaria var. Camarosa*). It was
252 concluded that the DIC treatment had a huge impact both on drying performances and
253 kinetics, compared to usual airflow drying (AFD). Moreover, the modified texture has
254 significantly improved the rehydration. Studies that correlate the drying time with airflow
255 velocity indicate a faster rehydration (Okos et al. 1992; McMinn and Magee 1997). This

256 reflects a reduction of shrink and thus a presence of well-defined higher intercellular
257 porosity which enhances the rehydration rate (Krokida and Philippopoulos 2005). In other
258 words, the rehydration rate may be used as food quality index. The dried product in optimal
259 conditions of SD (AFD+DIC+AFD) and FD result in a less damage of both structure and
260 composition which allow more rapidly and completely rehydrating when compared to
261 conventionally dried products (Chung and Lee 2015).

262 **3.2. Modeling of rehydration curves**

263 **3.2.1. Diffusive Model**

264 The effective diffusivity of pumpkin slices dried using different procedure has been
265 evaluated according to equation number (6), assuming that the thickness L is kept constant
266 over the entire rehydration process. Typical graphs of $\ln\left(\frac{M(t)-M_e}{M_0-M_e}\right)$ versus time t for
267 rehydration of pumpkin slices dried using different methods are plotted in Fig. 5 a), 5 b), 5 c)
268 et 5 d). The effective diffusivity of each sample has been concluded upon each curve slope.
269 Hence, the estimated values of D_{eff_1} , D_{eff_2} and D_{eff_3} are displayed in Table 3.

270 Under the used rehydration temperatures (3 values), the pumpkin slices dried using FD, SD
271 and VMFD presented higher effective diffusivities than those of AFD samples. It has been
272 also observed that the kinetic curves of FD, SD samples (Fig 5 c and 5 d), had three different
273 slopes each, suggesting three rehydration process stages (Table 3), according to the three
274 effective diffusion coefficients. D_{eff_1} Represents the beginning of rehydration and should be
275 compared to the starting accessibility, previously defined by numerous researchers (Allaf et
276 al. 2014b; Téllez-Pérez et al. 2014; Albitar et al. 2011), and averted the initial high-rate water
277 absorption. The second stage of D_{eff_2} represents the intermediary rehydration period,
278 characterized by a decreased water absorption rate. D_{eff_3} is The third and final stage of the

279 rehydration process where the rehydration rate was minimum. It should reveal the mass
280 transfer within the preserved cells. Hence, D_{eff_3} has showed a permeability through the
281 non-broken cell-walls.

282 The Freeze-Dried FD and Swell-Dried SD pumpkin slices presented the highest rehydration
283 rate, due to the great porosity, whatever the rehydration temperature. Indeed, the highest
284 rate of water absorption of pumpkin slices (D_{eff_1}) has been occurred, during the first
285 minutes of the rehydration. Since this rehydration stage should reveal the first interaction
286 between water and the matrix surface (similar to the starting accessibility). Following the
287 interpretation of the D_{eff_1} values' behavior, recorded under the rehydration temperatures
288 between 30°C and 60 °C (Table 3), it has been averred that the results obtained through the
289 AFD and VMFD methods increase gradually versus the increased rehydration temperature
290 values. In other hand, the D_{eff_1} values obtained through the SD and FD methods, under the
291 same rehydration temperature interval, show practically a constant value. Accordingly, it can
292 be concluded that the rehydration temperature has no effect on the D_{eff_1} , obtained by the
293 two last methods. However, it can be observed that the D_{eff_1} value obtained for the
294 rehydration temperature 45°C is over the normal value (around 60 m²/s). This wrong value is
295 certainly caused by insignificant delay on the rehydration time period (in few seconds).
296 Subsequently, the second decreasing rate revealed through D_{eff_2} lasted nearly two hours of
297 the process time and the samples reached a saturation level of water content apparently
298 without the third rehydration stage. By contrast, Figures 5 a) et 5 b), which correspond to
299 VMFD and AFD dried samples show after the initial water-surface interaction (D_{eff_1}) two
300 decreasing stages of curves of rehydration kinetics, thus suggesting two effective decreasing
301 rehydration diffusivities D_{eff_2} and D_{eff_3} (Table 3). This may probably divulge the shrinkage

302 of the whole structure, and the rehydration within the distorted cells. However, it was
303 observed that the three rehydration stages depend also on temperature. Rehydration time
304 decreases versus the temperature. Thus, by increasing the temperature from 30 to 60°C, the
305 first stage duration of AFD and VMFD became 20 and 35 min, respectively (Table 3). Similar
306 result was reported elsewhere (Cunningham et al. 2008). The diffusivity increases with
307 temperature of rehydration (Table 3). Similar behavior was observed for the rehydration at
308 low temperature of other vegetal products: Quinces (Noshad et al. 2011), Chilean Papaya
309 (*Vasconcellea pubescens*) (Zura et al. 2013a), onion (Debnath et al. 2004), potato cylinders
310 (Cunningham et al. 2008), potato cubes (Markowski et al. 2009), pear (chafer et al. 2011),
311 sour cherry (*Prunus cerasus* L.) (Aghbashlo et al. 2010).

312 The values of effective diffusivity D_{eff_1} , D_{eff_2} and D_{eff_3} obtained at 30, 45 and 60°C
313 allowed the calculation by means of linear regression (Eq.7) the values of D_{eff_0} and E_a . Can
314 be mentioned the AFD dried samples (Table 4):

315 $D_{eff_{10}} = 4.8955 \times 10^{-5} \text{m}^2 \text{s}^{-1}$, $D_{eff_{20}} = 8.1736 \times 10^{-5}$, $E_{a1} = 27.8$ (kJ/mol) and $E_{a2} = 28.0$ (kJ/mol).

316 The results of VMFD, SD, and FD dried samples, including correlation coefficients (R^2) are
317 assembled in Table 4. Several authors have expressed the influence of temperature on
318 rehydration in term of similar-Arrhenius relationship. The values of activation energy were
319 situated in the same range for other vegetal products: Aloe vera (*Aloe barbadensis* Miller)
320 (Vega-Gálvez et al. 2009), carrot (Planinic et al. 2005), basil (Demirhan and Özbek 2010),
321 Shiitake mushroom (*Lentinus edodes*) caps (García-Segovia et al. 2011), Chilean Papaya (Zura
322 et al. 2013a), broccoli stems (Sanjuan et al. 1999), Potato Cylinders (Cunningham et al.
323 2008), *Morchella esculenta* (morel) (García-Pascual et al. 2006), vegetable wastes (Lopez et
324 al. 2000).

325 **3.2.2. Empirical models.**

326 *3.2.2.1. Fitting of the rehydration curves*

327 In order to describe the rehydration kinetics of differently dried pumpkin slices using AFD,
328 VMFD, SD, and FD, four empirical models namely Peleg, Weibull, Exponential, and 1st-order
329 models have been used (Table 1).

330 The estimated A and B parameters through Weibull model, for given conditions are also
331 given in Table 2, and the fitting of experimental results are illustrated in Figures 4 a), 4 b), 4
332 c), and 4 d). Some researchers suggested that the parameter B represents the time
333 necessary to achieve 63% process (Marabi et al. 2003; Cunningham et al.2007; Machado et
334 al. 1999). For AFD, VMFD and SD dried of pumpkin slices, B-value varied from 3.872 to
335 67.378 min decreases when rehydration temperature increased from 30 to 60 °C. A similar
336 behavior was noticed in the case of other products: Ready-to-eat Breakfast Cereal (Machado
337 et al. 1999), Figs (Ansari et al. 2015). By contrast, in the case of FD dried samples,
338 rehydration rate and thus B-value increased by increasing temperature from 45°C. This may
339 be attributed to the sample collapse during the rehydration. In order to explain this
340 phenomenon, deep understanding of correlation between structure and mass transfer
341 phenomena during the rehydration is necessary. (Marabi et al. 2003) used Weibull
342 distribution model to comment their rehydration results. They concluded that the product
343 porosity of freeze-dried materials perfectly controlled the mass transfer. In case of low
344 porosity products (i.e. AFD-dried materials), the impact of rehydration temperature is
345 correlated with similar-Arrhenius evolution of diffusivity (Meda and Ratti 2005). A-value of
346 Weibull model should interpret the measure of water absorption rate at the beginning of the
347 process. A-value varies between 0.409 and 1.069 for all differently dried samples; these
348 values were situated in the same range of values reported by different researchers

349 (Cunningham et al. 2007; Athanasia and Konstantinos 2009) to be between 0.2 and 1.0. The
350 lower the value of A, the faster the water absorption rate.

351 Peleg model was also used to determine the parameters K_1 and K_2 . K_1 was considered as the
352 initial rehydration value, while K_2 the maximum water absorption capacity, the lowest values
353 of K_2 presented a great water absorption capacity as suggested by (Solomon 2007). With
354 increased temperature, K_1 slightly increased in linear manner in the case of AFD and VMFD
355 dried samples (Table 2), and decreased in non-linear manner in the case of SD and FD dried
356 samples. With increased temperature, K_2 decreased linearly in the case of AFD, VMFD and
357 SD dried samples (Table 2) and with non-linear manner in case of FD samples (Table 5).
358 Similar behavior has been found by other authors (Garcia-Pascual et al. 2006); Moreira et al.
359 2008). Besides that, the Tables 2 show a first order association and exponential models
360 which can also describe water absorption during rehydration of dried pumpkin slices. As can
361 be inferred, the kinetics constant of association of first order and exponential models
362 increased with increased temperature in linear manner in case of samples dried with AFD
363 and VMFD (Table 2 and 3), and non-linear in case of SD and FD dried samples (Table 2). This
364 implies a high velocity of rehydration at high temperature.

365 *3.2.2.2. Statistical Analysis of Models*

366 The statistical analyses were applied to these various models, proposed to rehydration
367 kinetics of dried pumpkin slices (Tables 2). Using non-linear regression analysis, different
368 model parameters have been determined involving their R^2 and RMSE values. The four
369 rehydration models yielded excellent results better than those obtained experimentally. In
370 our cases, the dried pumpkin slices (AFD, VMFD, SD, and FD), Weibull model provided the
371 highest R^2 , the lowest X^2 and RMSE values. This correlates several research works performed
372 on rehydration kinetics of different food products, who reported the high adjustment quality

373 obtained by using Weibull model: (Demiray and Tulek 2017; Demirhan and Özbek 2010;
374 Marabi et al. 2003).

375 **4. Conclusion**

376 In this current contribution, different drying methods namely; airflow drying (AFD), freeze-
377 drying (FD), swell-drying (SD) combining DIC between two stages of AFD and vacuum multi-
378 flash drying (VMFD) were studied. In this view, specific case of pumpkin slices have been put
379 into rehydration investigation. Following different tests, the obtained results averred that
380 the technique of drying has a significant effect on the rehydration kinetics. Under three
381 different rehydration temperature levels, it has been found that the AFD has the slowest
382 rehydration process, whilst, the FD, SD and VMFD resulted in reducing the rehydration time.
383 In other hand, it has been found that the FD and SD pumpkin slices presented the highest
384 rehydration rate through phenomenological diffusion model, characterized by three stages
385 (D_{eff_1} , D_{eff_2} and D_{eff_3}), and then, three effective diffusivities. This is due to the interaction
386 between water and matrix surface, high porosity, and penetration of cell wall. The highest
387 mass transfer rate has been recorded, during the first minutes of the rehydration. It then
388 decreases until the time during which the sample reached a saturation water content.
389 However, in case of AFD and VMFD slices dried using, the highest mass transfer occurred
390 after the first stage of rehydration process. This is caused by slices shrink, which may arise
391 during the ring process. The shrink slows down the diffusion of water from surface to the
392 center. The rehydration temperature dependency modeling was performed in adequate
393 manner, using the Arrhenius equation with two activation energy. In case of slices dried
394 using AFD and VMFD and three activation energy levels for the case of slices dried with SD
395 and FD.

396 Several empirical models were tested well analyze the rehydration kinetics. Weibull model
397 has shown the best fit upon the experimental results, highlighted by a highest R^2 coefficient,
398 the lowest χ^2 , the sum of square error and the root mean square error. They considered as
399 the best way for elucidating the rehydration characteristics of Dried pumpkin slices,
400 according to different drying methods; AFD, VMFD, SD and FD.
401 The selection of an appropriate drying technique upon adequate rehydration temperature is
402 necessary for a reliable rehydration process design, yielding high quality food products.
